# STELLAR GROUPS. II. THE $\zeta$ HERCULIS, $\epsilon$ INDI AND 6i CYGNI GROUPS OF HIGH-VELOCITY STARS 

Olin 7. Eggen

(Communicated by the Astronomer Royal)
(Received 1958 January r)

## Summary

A catalogue of 700 high-velocity stars has been searched for objects that share the well-determined space motions of $\zeta$ Herculis ( 22 stars), $\epsilon$ Indi ( 14 stars) and 6r Cygni ( 15 stars). The space motions of these groups can be summarized as follows (the Hyades and Sirius Groups of Paper I have been added for comparison):

| Group | A |  | D | $V_{t}$ | $U$ | $V$ | $W^{\top}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | h | m | 。 |  |  | $\mathrm{km} / \mathrm{sec}$ |  |
| Sirius | 20 | 44 | $-42 \cdot 7$ | $18 \cdot 4$ | - 14 | $\bigcirc$ | $-127$ |
| Hyades | 6 | 18 | + $7 \cdot 5$ | $44^{\circ}$ | +40 | - 18 | $-2$ |
| $\zeta$ Her | 5 | 48 | $-16 \cdot 5$ | $74 \cdot 5$ | $+54$ | -45 | -26 |
| $\epsilon$ Ind | 6 | 44 | + $6 \cdot 7$ | $88 \cdot 5$ | +79 | -39 | + 6 |
| 6i Cyg | 6 | 28 | $+0 \cdot 3$ | 108.0 | +92 | -53 | -6] |

where the values of $(A, D)$ represent the convergent points of the apparent motions and $V_{t}$ is the total space velocity of each group with respect to the Sun (the vector space velocities are in the direction $l=148^{\circ}, b=0^{\circ} ; l=58^{\circ}$, $b=0^{\circ}$; and $b=+90^{\circ}$ for $U, V$, and $W$ respectively). A search through the same catalogue for stars that might be " members" of synthetic groups with convergent point at $\delta=-90^{\circ}$ and $V_{t}=74.5,88 \cdot 5$, and $108 \mathrm{~km} / \mathrm{sec}$ indicated that only 2 or 3 chance members are expected to be included in each group.

The colour-luminosity array for the stars in all three high-velocity groups is very similar to that for the galactic cluster M 67 .

In igil Benjamin Boss (1912a) announced the discovery that a dozen stars or so of large proper motion formed a moving cluster with 61 Cygni. Further investigations by Boss (1912b) and by Russell (1912) appeared to establish the reality of the cluster but several years later when Rasmuson (192r) re-examined the evidence with the new material then available, he concluded that "there are great reasons to exclude from the list of moving clusters the 6I Cygni-stream . . .". Still later, Chaudhuri (1940) came to the same conclusion.

The purpose of the present investigation is not to re-hash the available data for the stars originally assigned to the 61 Cygni cluster but rather to search for stars sharing the well-determined space motions of selected high-velocity stars, including 6r Cygni. The stars chosen, for the accuracy of their proper motions, radial velocities and parallaxes, are as follows:

| Star | $\pi_{t}$ | $\underset{(\mathrm{km} / \mathrm{sec})}{\rho_{0}}$ | $\mu$ | $U$ | V | W |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\beta \mathrm{Hyi}$ | $0 \cdot 153$ | +22.9 | $2 \cdot 255$ | + 53 | -43 | -28 |
| $\zeta$ Her | $0 \cdot 101$ | $-69 \cdot 9$ | 0.608 | +54 | -47 | -24 |
| 6ı Cyg | 0.296 | $-64 \cdot 0$ | 5.205 | +92 | $-53$ | - 6 |
| $\epsilon$ Ind | $0 \cdot 285$ | $-40 \cdot 4$ | $4 \cdot 692$ | +79 | -39 | + 6 |

where the vector space velocities (galactic), $U, V$ and $W$, are directed toward $l=148^{\circ}, b=0^{\circ} ; l=58^{\circ}, b=0^{\circ}$; and $b=+90^{\circ}$, respectively. The catalogue searched consisted of 700 high-velocity stars, mainly from the lists published by Miczaika (1940) and by Roman (1955) but with a few additional stars obtained from recently published lists of radial velocities.

Since most of the trigonometric parallaxes for the high-velocity stars are much less accurately determined than those for the stars listed above, the method used for selecting group members was that described in a previous paper (Eggen 1958 ; Paper I). Stars were admitted to candidacy for membership in a group if the observed position angle of the proper motion, $\theta_{0}$, agreed with that computed from the group motion to the extent that $\Delta \theta \sin \lambda<10^{\circ}$, where $\lambda$ is the angular distance of the star from the convergent point $(A, D)$ of the group motion. The candidates were then admitted to group membership only if the difference, $\rho_{\mathrm{o}}-\rho_{\mathrm{c}}$, between the observed radial velocity, $\rho_{\mathrm{o}}$, and that computed from the group motion, $\rho_{\mathrm{c}}$, was less than, or equal to, 5,6 , or $7 \mathrm{~km} / \mathrm{sec}$, respectively, for radial velocities of quality $a, b$ or $c$, as defined by R. E. Wilson (r953).

The first two stars listed above, $\beta$ Hydi and $\zeta$ Herculis, obviously have a common space motion and the convergent point of what will be called the $\zeta$ Herculis Group was obtained from the mutual convergent point of the proper motions of these two stars. The values of $(A, D)$ for what will be called the 6I Cygni and $\epsilon$ Indi Groups are merely the apices of the motion of the defining stars, computed from the radial velocities, proper motions and parallaxes listed above. The three convergent points and total space velocities with respect to the Sun, $V_{t}$, are as follows (those for the Hyades and Sirius Groups, discussed in Paper I, are added for comparison):

| Group | $A$ |  | $D$ | $V_{t}$ |
| :--- | ---: | ---: | ---: | ---: |
|  | h | m | $\circ$ | $\mathrm{~km} / \mathrm{sec}$ |
| Sirius | 20 | 44 | $-42 \cdot 7$ | $\mathrm{r} 8 \cdot 4$ |
| Hyades | 6 | 18 | $+7 \cdot 5$ | $44 \cdot 0$ |
| $\zeta$ Her | 5 | 48 | $-16 \cdot 5$ | $74 \cdot 5$ |
| $\epsilon$ Ind | 6 | 44 | $+6 \cdot 7$ | $88 \cdot 5$ |
| 6 I Cyg | 6 | 28 | $+0 \cdot 3$ | $108 \cdot 0$ |

Eight per cent, or 54 , of the 700 stars examined were found to be members of the three high-velocity groups as follows: $\zeta$ Herculis, 23 members; $\epsilon$ Indi, 15 members; and 6i Cygni, 16 members. The members of the $\zeta$ Herculis, $\epsilon$ Indi and 6 I Cygni Groups are listed in Tables I, II and III, respectively, together with the observed position angle of the proper motion, $\theta_{0}$, and the normalized residual from the computed value, $\Delta \theta \sin \lambda$; the observed radial velocity, $\rho_{0}$, and its residual, $\Delta \rho$, and quality Q ; the total annual proper motion $\mu$; the group parallax $\pi_{\mathrm{g}}$, computed from $4.738 \mu / V_{t} \sin \lambda$; the observed magnitude and colour $V_{E}$ and $(P-V)_{E}$; and the spectral type and visual absolute magnitude, $M_{v}$. The proper motions are mainly uncorrected values from the General Catalogue (Boss 1937) except for a few stars from the Yale zones or unpublished Greenwich determinations. The radial velocities and their quality have been taken from Wilson's (1953) catalogue. The magnitudes and colours were observed on the $(P, V)_{E}$ system or reduced to that system from observations by Roman (1955) or by Stoy and his collaborators (cf. Evans, Menzies and Stoy 1957). The spectral types are mainly by Roman (1955).

As a test of the possibility that the group members might be so classified by chance coincidences of $\theta_{0}$ and $\rho_{0}$ with $\theta_{\mathrm{c}}$ and $\rho_{\mathrm{c}}$, the same catalogue of 700 stars. was examined for "members" of a synthetic group with convergent point $\delta=-90^{\circ}$. The galactic coordinates of this convergent, $l=270^{\circ}$ and $b=-28^{\circ}$, place it near the centre of that hemisphere of the sky toward which the velocity vectors of the high-velocity stars show a strong preference (Oort 1926). Eleven per cent, or 76 of the 700 stars examined for membership in the synthetic group gave values of $\Delta \theta \sin \lambda<10^{\circ}$. When the criterion that $\Delta \rho \leqslant 5,6$, or $7 \mathrm{~km} / \mathrm{sec}$ for stars of quality $\mathrm{a}, \mathrm{b}$, and c , respectively, was applied, the following " members'" were obtained for three values of $V_{t}$ :

$$
\begin{array}{rlrr}
V_{t}(\mathrm{~km} / \mathrm{sec}) & =74 \cdot 5 & 88 \cdot 5 & 108 \\
\text { No. } & =3 & (\mathrm{I}) & 3
\end{array}
$$

The one " member" for $V_{t}=88.5 \mathrm{~km} / \mathrm{sec}$, shown in parentheses, is a star with a small radial velocity of quality c that also satisfies the requirements for the group with $V_{t}=74.5 \mathrm{~km} / \mathrm{sec}$. Apparently, we might expect two or three accidental members to the groups in Tables I-III but it does not seem possibleto dismiss all the members as spurious.

Because of the proximity of the apparent convergent points of the three high-velocity groups, there is some ambiguity in assigning four stars to a particular group. These stars, together with the appropriate values of $\Delta \theta \sin \lambda$, $\Delta \rho$ (in $\mathrm{km} / \mathrm{sec}$ ) and $\pi \mathrm{g}$, are as follows:

|  | $\zeta$ Herculis |  |  | 6r Cygni |  |  | $\epsilon$ Indi |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\Delta \theta \sin \lambda$ | $\Delta \rho$ | $\pi_{\mathrm{g}}$ | $\Delta \theta \sin \lambda$ | $\Delta \rho$ | $\pi_{\mathrm{g}}$ | $\Delta \theta \sin \lambda$ | $\Delta \rho$ | $\pi_{\mathrm{g}}$ |
| $\eta$ Ret | $-2^{\circ}$ | -3 | $\bigcirc{ }^{\circ \prime} 016$ | $-8^{\circ}$ | +5 | ".009 | 。 |  | " |
| HD 66171 |  |  |  | $\bigcirc$ | +6 | 0.023 | +3 | +2 | 0.030 |
| HDro2365 |  |  |  | +7 | - | 0.070 | - | +4 | 0.0855 |
| HDio4988 |  |  |  | +6 | +2 | 0.023 | - 1 | - 1 | 0.028 |

The assignment of these stars to the groups in Tables I-III has been guided by the trigonometric values of the parallaxes.

Also, there are two high-velocity white dwarfs that may belong to either the 6I Cygni or $\epsilon$ Indi Groups, but because of (r) the uncertainty in the observed radial velocities of these faint stars with poor spectral lines and (2) the possibility that the observed line-shifts do not represent the true radial velocity, it is not. possible to assign them definitely to either group. These stars are as follows:

|  |  |  |  | Cygni |  |  | Indi |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\pi_{t}$ | (p.e.) | $\Delta \theta \sin \lambda$ | $\Delta \rho$ | $\pi_{\mathrm{g}}$ | $\Delta \theta \sin \lambda$ | $\Delta \rho$ | $\pi_{\mathrm{g}}$ |
| $-32^{\circ} 5613$ | $0 \cdot 108$ | 0.0007 | +8 | $(-18)$ | $\bigcirc$-.104 | + 1 | (-I) | $0^{\circ} \mathrm{O} .122$ |
| Li534-r | $0 \cdot 059$ | 0.005 | + | (-6) | 0.068 | +6 | $(+4)$ | $0 \cdot 100$ |

The mean trigonometric parallaxes, $\pi_{i}$, indicate that both stars may belong to the 6i Cygni Group.

Since the observed parallaxes of the stars, except 6i Cygni, $\epsilon$ Indi, and the four stars mentioned above, were not used in assigning the members to the groups, a comparison between these and the group parallaxes offers an additional test of the reality of the groups. The parallaxes are listed in Table IV, where the absolute trigonometric values, $\pi_{t}$, were taken from the Yale Parallax Catalogue-

(Jenkins 1952) and the group parallaxes, $\pi_{\mathrm{g}}$, from Tables I-III; the abbreviations used to designate the source of the individual trigonometric values are those given by Jenkins. Because of the large scatter in the trigonometric values, there is probably no star in Table IV that could be eliminated as a group member on
the basis of this comparison. It is noteworthy that of the 600 stars within 20 parsecs of the Sun for which radial velocities have been determined (Gliese 1957) eight per cent belong to the Hyades, $\zeta$ Herculis, $\epsilon$ Indi or 6i Cygni Groups.

The colour-luminosity array for the stars in Tables I-III is shown in Fig. I, where the $\zeta$ Herculis, $\epsilon$ Indi and 61 Cygni Group members are indicated by crosses, open circles and filled circles, respectively. The standard main sequence (Eggen 1955) is shown with a half-width of $o^{\mathrm{m} \cdot 2}$. This colour-luminosity array

Fig. 1.-Colour-luminosity array for stars in the $\zeta$ Herculis (crosses), $\epsilon$ Indi (open circles), and 61 Cygni (filled circles) Groups.
is almost identical with that obtained from the members of the cluster M67 (Johnson and Sandage 1955) and, indeed, nearly every group star in Fig. I can be matched in colour and in luminosity by a member of the M67 cluster except for the five bright stars near $M_{v} \sim-\mathrm{I}^{\mathrm{m}}$ and $(P-V)_{E} \sim+\mathrm{I}^{\mathrm{m}} \cdot 5$ to $+\mathrm{r}^{\mathrm{m}} \cdot 6$, which occur in the groups but not in the cluster. These M-type giants, members of the $\zeta$ Herculis Group, are mainly known (irregular) or suspected light variables.

In the notation of a previous paper (Woolley and Eggen 1958) the galactic orbits of the members of these high-velocity groups are of class $D$, that is, the pericentric distances of the stars are between two-thirds and one-half of their present distances from the galactic centre.

I am greatly indebted to Mr J. Alexander, Miss L. Mather and Miss A. F. Heather for much computational assistance.

Royal Greenwich Observatory,
Herstmonceux Castle, Sussex:
1957 December 30.
